What stood out to me is that these four matrices from the **Loss of Divinity** section seem to echo the same values that keep showing up in my route: **10, 12, and 14.**

That caught my attention because, in my 27×27 map, (14,14) is the exact center of the whole matrix, and that cell is ****NG****. In the route itself, ****I = 10, $\phi(\text{NG}) = 12$, and $10 + \phi(10) = 14$.**

So seeing those same values appear together here — especially with 14 in the center — feels worth looking at more closely. I'm not calling it proof, but the overlap is definitely interesting.

****I have an interesting theory about what the five-point drawings may actually represent.****

Jung's **Liber Primus**, the first part of The Red Book, describes his journey into the unconscious. In the opening sections, Jung realizes that he has lost contact with his own soul and that the answers he is looking for cannot come from the outside world. He has to turn inward and follow a path that he does not fully understand.

The first chapters gradually prepare him for this journey: he rediscovers his soul, questions the authority of his conscious mind, and learns that he cannot rely only on reason or on familiar ways of thinking.

Then comes The Desert, the **fifth** major section if the prologue is counted. This is the first point where the journey becomes a problem of **orientation**. Jung finds himself in an empty, unfamiliar inner landscape. There are no clear landmarks, **no obvious direction**, and no way to know in advance where the path will lead. The old way of navigating no longer works, so he has to find his direction from within.

This is why the repeated **five-point drawings** in Cicada 3301's Liber Primus may be significant. The number five may point directly to this stage of Jung's Liber Primus, while the drawing itself may represent the same idea visually: a set of points used to orient yourself inside a space where the path is hidden.

This becomes especially interesting if Cicada's Liber Primus is not meant to be read only as a linear text, but as a structure that must be navigated. In that case, the five points may not simply be decorative symbols. They may be telling us how to think about the book: not as a sequence of lines, but as a space with positions, directions, and a path that has to be discovered.

A particularly interesting closure appears **inside COLD** itself.

Using the same GP-index sum mod 29 operation already used earlier:

$$\begin{aligned} \text{**G + J + EA + A} &= 6 + 11 + 28 + 24 = 69 \\ 69 \bmod 29 &= 11 = \text{J**} \end{aligned}$$

For the plaintext:

$$\begin{aligned} \text{**C + O + L + D} &= 5 + 3 + 20 + 23 = 51 \\ 51 \bmod 29 &= 22 = \text{OE**} \end{aligned}$$

So:

Ciphertext COLD -> J

Plaintext COLD -> OE

This is striking because J and OE are exactly the centers of the first two major 3-rune nodes, and

both satisfy:

$$**\phi(J) = 10 = I**$$

$$**\phi(OE) = 10 = I**$$

So COLD may contain a built-in structural callback to the beginning of the route, converging **once** again on I.

I think I may have found something very very significant 🔥

1. The basic pattern

I noticed a simple pattern between the main totient structures.

Many important nodes have the form:

a-b-a

Then the center value seems to become the outer value of the next node:

a-b-a → b-c-b

So each new node appears to inherit one value from the previous node and introduce one new value in the center.

2. First clear example

The node X-I-X gives:

$$\phi(X)=6, \phi(I)=4, \phi(X)=6 \rightarrow 6-4-6$$

Later, H-NG-C/K gives:

$$\phi(H)=4, \phi(NG)=12, \phi(C/K)=4 \rightarrow 4-12-4$$

So the center value 4 from the first structure becomes the outer value of the next:

$$**6-4-6 \rightarrow 4-12-4**$$

The old value is carried forward, and 12 is introduced as the new center.

3. The same pattern appears after COLD

At the end of COLD, we find the mirrored node:

EA-A-EA

Applying the center-totient rule:

$A=24 \rightarrow \phi(24)=8=H$

gives:

EA-H-EA

Its totient signature is:

$\phi(EA)=12, \phi(H)=4, \phi(EA)=12 \rightarrow 12-4-12$

So the same inheritance happens again:

$4-12-4 \rightarrow 12-4-12**$**

The center value 12 becomes the outer value of the next structure.

This gives a clean sequence:

$6-4-6 \rightarrow 4-12-4 \rightarrow 12-4-12$

following:

$a-b-a \rightarrow b-c-b$

4. The values also form a chain

The important values seem to be passed forward:

****10 → 4 → 12 → 4 → 1****

10 comes from $\phi(J)=10$ and $\phi(OE)=10$.

Then $\phi(10)=4$.

Later, NG gives $\phi(NG)=12$, and TH gives $\phi(TH)=1$.

So each stage may simply introduce a new value, while the next structure inherits the previous one.

X-I-X	→	6-4-6
H-NG-C/K	→	4-12-4
EA-H-EA	→	12-4-12
H-U-H	→	4-1-4

6	-	4	-	6						
		↓								
		4	-	12	-	4				
				↓						
				12	-	4	-	12		
						↓				
						4	-	1	-	4

5. Why this matters

If this pattern is real, the nodes may be part of one connected chain rather than separate clues.

Each node seems to:

- * inherit one value from the previous stage;
- * introduce one new value for the next stage.

Then the new value is carried forward.

So after COLD, instead of looking for a completely new rule, we should look for the next structure that continues this same inheritance pattern.

These are not just any decryption nodes — they are the nodes that produce the movement / shift values used to move the route to the next stage.

1. X-I-X

After AS I GO THE, the final X opens:

X-OE-X → X-I-X

Its totient signal is:

6-4-6

The important transition value here is 4. That value is then inherited by the next movement-producing node.

2. H-NG-C/K

This node gives:

4-12-4

Here, the inherited 4 becomes the outer value, while 12 becomes the new movement value used to continue the route toward COLD.

So:

6-4-6 → 4-12-4

3. EA-H-EA after COLD

At the end of COLD, we find:

EA-A-EA → EA-H-EA

Its totient signal is:

12-4-12

Again, the previous movement value 12 becomes the outer value of the next transition node:

4-12-4 → 12-4-12

4. What it predicts

So the transition nodes seem to follow:

a-b-a → b-c-b

The center value of one movement-producing node becomes the outer value of the next.

The current signal is:

12-4-12

So the next transition node should naturally have the form:

4-?-4

And we already know one important node that produces exactly that:

H-TH-H → H-U-H → 4-1-4

So the totient inheritance chain may be pointing back to H-TH-H after COLD.

6-4-6 → 4-12-4 → 12-4-12 → 4-1-4

The key point is that this pattern is about the nodes that generate the shifts / movement values between stages, not every key used only for decryption.

What is interesting is that the pattern skips the COLD key H-U-H.

That may be because H-U-H only decrypts COLD; it does not move the route away from A. The actual shift from A is already given by $\phi(NG)=12$.

So the inheritance may apply only to movement/transition nodes, while local decryption keys like H-U-H are skipped.

Either way, it's an interesting connection. The totients clearly seem to link the structures somehow. I feel like the system must have some kind of underlying control mechanism, even if it's very subtle

The most interesting part is that this finding points toward H-TH-H, which is exactly where I had already found a continuation before. At the time, though, I didn't yet understand how the structures might be pointing to one another

Moreover, the 12-4-12 pattern from EA-H-EA also works as a clean geometric route to the center of H-TH-H.

Starting from the upper EA of the original EA-A-EA structure at (10,7):

- RIGHT 12 → (10,19)
- DOWN 4 → A crossroads at (14,19)
- DOWN 12 → (26,19), the exact center TH of H-TH-H.

So 12-4-12 is not just a numerical signature. It can also be read directly as a movement instruction on the 27×27 map, leading through the already established A crossroads and landing exactly on another structure that is independently important to the decryption.

That makes the connection especially interesting, the same pattern appears both mathematically and geometrically, which may be another intentional clue built into the structure.

I think this is probably just an early geometric hint from the creator.

My current idea is that the real structure works like a network of nodes connected by totient patterns. One node leads into another and passes part of its structure forward

I spent the entire day testing different possibilities, checking this structure from every angle, and trying to break it, but I could not. It still holds. Up to COLD, it remains the strongest structure I have

found.

I then tried to find an alternative continuation after COLD, but after testing many possibilities, one branch still stands out as clearly the strongest: I MAY CRY.

This is where I am ending Volume 2. Finding further continuation is extremely difficult, so I MAY CRY will serve as the new starting point for future analysis.

COLD ends at A(11,7). That cell is immediately inside the mirrored structure EA-A-EA, whose totient signature is 12-8-12 because $\phi(EA)=12$ and $\phi(A)=8$. This matters because the future I MAY key, NG-T-NG, has **exactly the same signature: 12-8-12.**

The COLD key comes from H-TH-H $\rightarrow$ H-U-H, since $\phi(TH)=1=U$. The totient signal of H-U-H is 4-1-4. Starting from the final A of COLD, that signal gives D4 $\rightarrow$ S(15,7), then R1 $\rightarrow$ B(15,8).

B is the center of the mirrored structure NG-B-NG. Compiling the center gives $\phi(B=17)=16=T$, so NG-B-NG becomes NG-T-NG. Its totient signature is again 12-8-12, exactly matching the EA-A-EA structure already present at the endpoint of COLD:

EA-A-EA $\rightarrow$ 12-8-12 $\leftarrow$ NG-T-NG

For NG-T-NG, $\mu(12)=0$, $\mu(8)=0$, $\mu(12)=0$, **so the Möbius phase is 0.** Therefore the key is not rotated.

The three possible cyclic phases give:

phase 0 $\rightarrow$ I MAY

phase 1 $\rightarrow$ S X A TH

phase 2 $\rightarrow$ I X F Y

So the Möbius rule independently selects the only phase that produces I MAY; the readable phase is not chosen afterward.

The algorithm then returns to the preserved H-TH-H route. Reading left from its center gives the ciphertext TH-G-T-E. Using the repeating key NG-T-NG-NG:

TH - NG = I

G - T = M
T - NG = A
E - NG = Y

So the result is:

****I MAY****

In compact form:

****H-TH-H → H-U-H → 4-1-4 → D4/R1 → NG-B-NG → NG-T-NG → phase 0 → TH-G-T-E → I MAY****

The strongest structural confirmation is that the endpoint of COLD already contains EA-A-EA → 12-8-12, the exact same totient signature as the key that decrypts I MAY.

After I MAY, the final ciphertext rune E(26,16) immediately forms the mirrored node ****E-X-E.****

Compile the center:

$\phi(X=14)=6=G$

So:

****E-X-E -> E-G-E****

Its totient signature is:

6-2-6

Möbius gives:

$\mu(6)=+1, \mu(2)=-1, \mu(6)=+1$

****so the phase is 1,**** and the active key becomes:

****G-E-E****

Using the inherited value 6:

****X(25,16) -> U6 -> J(19,16)****

J is the center of ****OE-J-OE**** Reading upward gives:

****J-OE-S****

Decrypting with G-E-E:

J-G = C

OE-E = R

S-E = Y

Result:

****CRY****

The three phases give:

****phase 0 -> OE T Y****

****phase 1 -> C R Y****

****phase 2 -> OE R N****

So the Möbius rule independently selects the only phase that produces CRY.

Compact flow:

****I MAY -> E-X-E -> E-G-E -> 6-2-6 -> phase 1 -> U6 -> J-OE-S -> CRY****

Moreover, I think special attention should be paid to the 3-rune nodes that have already been found or traversed, as well as to the geometry and spatial arrangement of the discovered keys that were not generated directly from 3-rune nodes. I marked those keys in blue.

Updated 27×27 working grid:

From my analysis, there appear to be two types of keys:

1. Direct keys — generated directly from mirrored 3-rune nodes.
2. Hidden keys — their locations are revealed by the totient masks of 3-rune nodes, which provide a precise route to them.

****1. H-NG-C****

This key is revealed by two inherited values from the previous structure. The chain $OE \rightarrow 10 = I \rightarrow \phi(I) = 4$ gives the linked values ****10 and 4.**** From the crossroads A(14,19), the value 4 moves to NG(14,23). Then the inherited value 10 defines the vertical span around that NG: H lies 10 cells above and C lies 10 cells below. This reconstructs the hidden key ****H-NG-C.****

****2. NG-B-NG****

The COLD key H-U-H is generated from the parent structure H-TH-H and produces the totient mask ****4-1-4.**** After COLD, those values are reused as movement: from the final A(11,7), D4 and then R1 lands exactly on B(15,8). That B is the center of the hidden mirrored structure ****NG-B-NG.**** Compiling the center with $\phi(B)=T$ produces the new key ****NG-T-NG.****

The important connection is that this new key is then applied back to the same preserved parent structure H-TH-H that previously generated H-U-H for COLD. Reading left from its center gives TH-G-T-E, and decrypting it with NG-T-NG produces ****I MAY.****

So the chain is:

****H-TH-H $\rightarrow$ H-U-H $\rightarrow$ COLD $\rightarrow$ 4-1-4 $\rightarrow$ NG-B-NG $\rightarrow$ NG-T-NG $\rightarrow$ return to H-TH-H $\rightarrow$ I MAY****

****Conclusion:**** specific totient values are reused as movement steps that lead to hidden keys. We can see which values are used in these cases, but the exact rule that determines when this mechanism is activated is still unknown.

Moreover, I found that

1. If the discovered key is ****non-mirrored,**** the center is not transformed by the totient and the key is used directly. For example:

H-NG-C $\rightarrow$ H-NG-C

2. If the discovered key is ****mirrored,**** the totient is applied to the center first, producing the actual key. For example:

NG-B-NG $\rightarrow \phi(B)=T \rightarrow$ NG-T-NG

In other words, the entire algorithm seems almost obsessed with symmetry. Wherever a mirrored structure appears, totients also appear, quietly controlling the structure and the movement through the grid
